Quad-Channel, 16-Bit, 1.25 GSPS Digital-to-Analog Converter (DAC)

Check for Samples: DAC3484

FEATURES

- **Very Low Power: 1.2 W at 1.25 GSPS, Full Operating Conditions**
- **Multi-DAC Synchronization**
- **Selectable 2x, 4x, 8x, 16x Interpolation Filter**
  - **Stop-Band Attenuation > 90 dBc**
- **Flexible On-chip Complex Mixing**
  - **Two Independent Fine Mixers with 32-bit NCOs**
  - **Power Saving Coarse Mixers: ± n×Fs/8**
- **High Performance, Low Jitter Clock Multiplying PLL**
- **Digital I and Q Correction**
  - **Gain, Phase, Offset, and Group Delay Correction**
- **Digital Inverse Sinc Filter**
- **Flexible 16-Bit LVDS Input Data Bus**
  - **8 Sample Input FIFO**
  - **Data Pattern Checker**
  - **Parity Check**
  - **GC5330 Compatible**
- **Temperature Sensor**
- **Differential Scalable Output: 10mA to 30mA**
- **Space Saving Package: 88-pin 9x9mm mRQFN (GREEN / Pb-Free)**

APPLICATIONS

- **Cellular Base Stations**
- **Diversity Transmit**
- **Wideband Communications**

DESCRIPTION

The DAC3484 is a very low power, high dynamic range, quad-channel, 16-bit digital-to-analog converter (DAC) with a sample rate as high as 1.25 GSPS.

The device includes features that simplify the design of complex transmit architectures: 2x to 16x digital interpolation filters with over 90 dB of stop-band attenuation simplify the data interface and reconstruction filters. Independent complex mixers allow flexible carrier placement. A high-performance low jitter clock multiplier simplifies clocking of the device without significant impact on the dynamic range. The digital Quadrature Modulator Correction (QMC) enables complete IQ compensation for gain, offset, phase and group delay between channels in direct up-conversion applications.

Digital data is input to the device through a 16-bit LVDS data bus with on-chip termination. The device includes a FIFO, data pattern checker and parity test to ease the input interface. The interface also allows full synchronization of multiple devices.

The device is characterized for operation over the entire industrial temperature range of –40°C to 85°C and is available in a very-small 88-pin 9x9mm mRQFN package.

The DAC3484 very low power, small size, superior crosstalk, high dynamic range and features are an ideal fit for systems with multiple transmit channels.
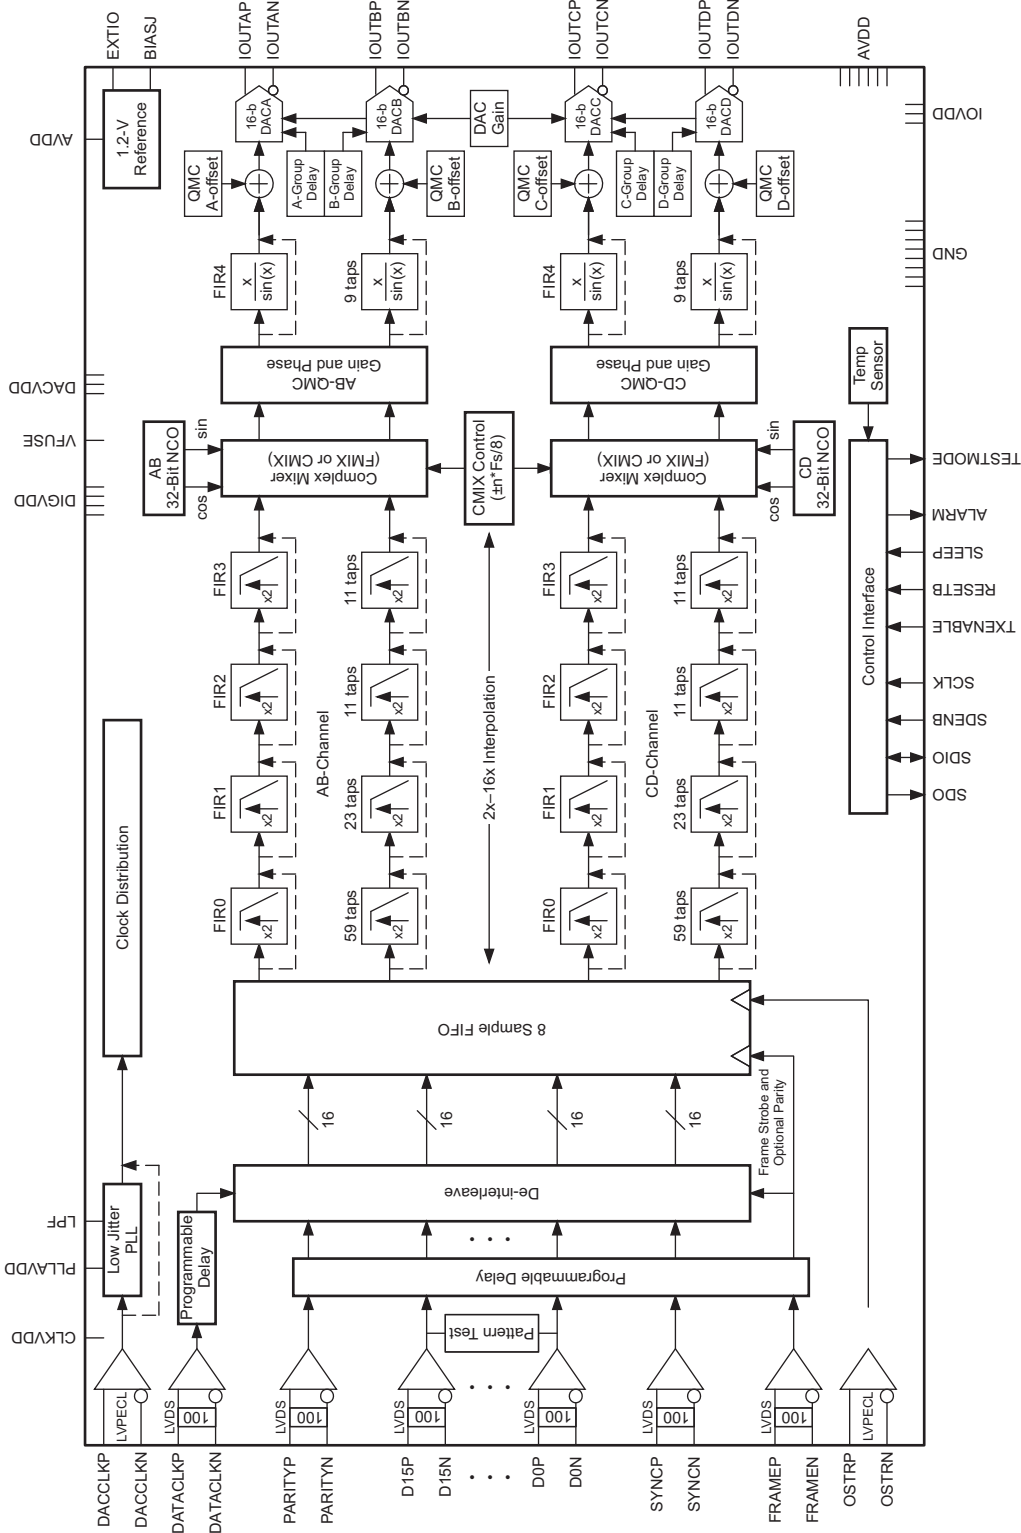

PRODUCT PREVIEW

PRODUCT PREVIEW information concerns products in the formative or design phase of development. Characteristic data and other specifications are design goals. Texas Instruments reserves the right to change or discontinue these products without notice.

PRODUCT PREVIEW

PIN FUNCTIONS

PIN NAME	PIN NO.	I/O	DESCRIPTION
AVDD	A36, A37, A38, A40, A41, A42, B31	I	Analog supply voltage. (3.3 V)
ALARM	B29	O	CMOS output for ALARM condition. The ALARM output functionality is defined through the *config7* register. Default polarity is active low, but can be changed to active high via *config0 alarm_out_pol* control bit.
BIASJ	A33	O	Full-scale output current bias. For 30mA full-scale output current, connect 1.28kΩ to ground. Change the full-scale output current through *coarse_dac(3:0)* in *config3, bit<15:12>*
CLKVDD	A4	I	Internal clock buffer supply voltage. (1.2 V) It is recommended to isolate this supply from DIGVDD and DACVDD.

D[15..0]P	A7, A8, B9, B10, A12, A13, A14, A15, B17, B18, B19, B20, A23, A24, B23, B24	I	LVDS positive input data bits 0 through 15. Internal 100 Ω termination resistor. Data format relative to DATACLKP/N clock is Double Data Rate (DDR).
			
			    D15P is most significant data bit (MSB)
			    D0P is least significant data bit (LSB)
			
			The order of the bus can be reversed via *config2 revbus* bit.

D[15..0]N	B7, B8, A10, A11, B11, B12, B13, B14, A19, A20, A21, A22, B21, B22, A26, A27	I	LVDS negative input data bits 0 through 15. (See D[15:0]P description above)
DACCLKP	A3	I	Positive external LVPECL clock input for DAC core with a self-bias.
DACCLKN	B3	I	Complementary external LVPECL clock input for DAC core. (see the DACCLKP description)
DACVDD	A35, A39, A43	I	DAC core supply voltage. (1.2 V). It is recommended to isolate this supply from CLKVDD and DIGVDD.
DATACLKP	A16	I	LVDS positive input data clock. Internal 100 Ω termination resistor. Input data D[15:0]P/N is latched on both edges of DATACLKP/N (Double Data Rate).
DATACLKN	B15	I	LVDS negative input data clock. (See DATACLKP description)
DIGVDD	A6, A9, A25, A28	I	Digital supply voltage. (1.2 V). It is recommended to isolate this supply from CLKVDD and DACVDD.
EXTIO	A34	I/O	Used as external reference input when internal reference is disabled through *config27 extref_ena* = '1'. Used as internal reference output when *config27 extref_ena* = '0' (default). Requires a 0.1 µF decoupling capacitor to AGND when used as reference output.
FRAMEP	B16	I	LVDS frame indicator positive input. Internal 100 Ω termination resistor. The main functions of this input are to reset the FIFO pointer or to be used as a syncing source. These two functions are captured with the rising edge of DATACLKP/N. The signal captured by the falling edge of DATACLKP/N can be used as a block parity bit. The FRAMEP/N signal should be edge-aligned with D[15:0]P/N. Additionally it is used to indicate the beginning of the frame.
FRAMEN	A18	I	LVDS frame indicator negative input. (See the FRAMEP description)
GND	C1, C2, C3, C4, Thermal Pad	I	These pins are ground for all supplies.
IOUTAP	B39	O	A-Channel DAC current output. Connect directly to ground if unused.
IOUTAN	B38	O	A-Channel DAC complementary current output. Connect directly to ground if unused.
IOUTBP	B36	O	B-Channel DAC current output. Connect directly to ground if unused.
IOUTBN	B37	O	B-Channel DAC complementary current output. Connect directly to ground if unused.
IOUTCP	B35	O	C-Channel DAC current output. Connect directly to ground if unused.
IOUTCN	B34	O	C-Channel DAC complementary current output. Connect directly to ground if unused.
IOUTDP	B32	O	D-Channel DAC current output. Connect directly to ground if unused.
IOUTDN	B33	O	D-Channel DAC complementary current output. Connect directly to ground if unused.

Product Folder Link(s): DAC3484

PIN FUNCTIONS (continued)

PIN NAME	PIN NO.	I/O	DESCRIPTION
IOVDD	B6, A17, B25	I	Supply voltage for all digital I/O. (3.3 V)
LPF	A1	I/O	PLL loop filter connection. If not using the clock multiplying PLL, the LPF pin can be left unconnected.
OSTRP	A2	I	LVPECL output strobe positive input. This positive/negative pair is captured with the rising edge of DACCLKP/N. It is used for multiple DAC synchronization. If unused it can be left unconnected.
OSTRN	B2	I	LVPECL output strobe negative input. (See the OSTRP description)
PARITYP	B26	I	Optional LVDS positive input parity bit. The PARITYP/N LVDS pair has an internal 100 Ω termination resistor. If unused it can be left unconnected.
PARITYN	A29	I	Optional LVDS negative input parity bit.
PLLAVDD	B1	I	PLL analog supply voltage. (3.3 V)
SCLK	A31	I	Serial interface clock. Internal pull-down.
SDENB	B28	I	Active low serial data enable, always an input to the DAC3484. Internal pull-up.
SDIO	A30	I/O	Serial interface data. Bi-directional in 3-pin mode (default) and 4-pin mode. Internal pull-down.
SDO	B27	O	Uni-directional serial interface data in 4-pin mode. The SDO pin is tri-stated in 3-pin interface mode (default).
SLEEP	B40	I	Active high asynchronous hardware power-down input. Internal pull-down.
SYNCP	A5	I	Optional LVDS SYNC positive input. The SYNCP/N LVDS pair has an internal 100 Ω termination resistor. If unused it can be left unconnected.
SYNCN	B5	I	Optional LVDS SYNC negative input.
RESETB	B30	I	Active low input for chip RESET, which resets all the programming registers to their default state. Internal pull-up.
TXENABLE	A32	I	Transmit enable active high input. Internal pull-down. To enable analog output data transmission, set *sif_txenable* in register *config3* to "1" or pull CMOS TXENABLE pin to high. To disable analog output, set *sif_txenable* to "0" **and** pull CMOS TXENABLE pin to low. The DAC output is forced to midscale.
TESTMODE	A44	I	This pin is used for factory testing. Internal pull-down. **Leave unconnected for normal operation.**
VFUSE	B4	I	Digital supply voltage. This supply pin is also used for factory fuse programming. **Connect to DACVDD for normal operation.**

Peak input current (any input)			20	mA
Peak total input current (all inputs)			−30	mA
Operating free-air temperature range, T_A: DAC3484		−40	85	°C
Storage temperature range		−65	150	°C
Lead temperature 1,6 mm (1/16 inch) from the case for 10 seconds			260	°C

(1) Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only and functional operation of these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) Measured with respect to GND.

THERMAL INFORMATION

	THERMAL METRIC[1]	DAC3484 RKD PACKAGE (88) PINS	UNITS
T_J	Maximum junction temperature	125	°C
θ_{JA}	Junction-to-ambient thermal resistance[2]	22.1	°C/W
θ_{JCtop}	Junction-to-case (top) thermal resistance[3]	7.1	
θ_{JCbot}	Junction-to-case (bottom) thermal resistance[4]	0.6	
θ_{JB}	Junction-to-board thermal resistance[5]	4.7	
ψ_{JT}	Junction-to-top characterization parameter[6]	0.1	
ψ_{JB}	Junction-to-board characterization parameter[7]	4.6	

(1) For more information about traditional and new thermal metrics, see the *IC Package Thermal Metrics* application report, SPRA953.
(2) The junction-to-ambient thermal resistance under natural convection is obtained in a simulation on a JEDEC-standard, high-K board, as specified in JESD51-7, in an environment described in JESD51-2a.
(3) The junction-to-case (top) thermal resistance is obtained by simulating a cold plate test on the package top. No specific JEDEC-standard test exists, but a close description can be found in the ANSI SEMI standard G30-88.
(4) The junction-to-case (bottom) thermal resistance is obtained by simulating a cold plate test on the exposed (power) pad. No specific JEDEC standard test exists, but a close description can be found in the ANSI SEMI standard G30-88.
(5) The junction-to-board thermal resistance is obtained by simulating in an environment with a ring cold plate fixture to control the PCB temperature, as described in JESD51-8.
(6) The junction-to-top characterization parameter, ψ_{JT}, estimates the junction temperature of a device in a real system and is extracted from the simulation data for obtaining θ_{JA}, using a procedure described in JESD51-2a (sections 6 and 7).
(7) The junction-to-board characterization parameter, ψ_{JB}, estimates the junction temperature of a device in a real system and is extracted from the simulation data for obtaining θ_{JA}, using a procedure described in JESD51-2a (sections 6 and 7).

$t_{s(SYNC\_PLL)}$	Setup time, SYNCP/N valid to rising edge of DACCLKP/N			200		ps
$t_{h(SYNC\_PLL)}$	Hold time, SYNCP/N valid after rising edge of DACCLKP/N			300		ps
TIMING SERIAL PORT						
$t_{s(SDENB)}$	Setup time, SDENB to rising edge of SCLK		20			ns
$t_{s(SDIO)}$	Setup time, SDIO valid to rising edge of SCLK		10			ns
$t_{h(SDIO)}$	Hold time, SDIO valid to rising edge of SCLK		5			ns
$t_{(SCLK)}$	Period of SCLK	Register *config6* read (temperature sensor read)	1			µs
		All other registers	100			ns
$t_{d(Data)}$	Data output delay after falling edge of SCLK			10		ns
t_{RESET}	Minimum RESETB pulsewidth			25		ns

(3) OSTR is required in Dual Sync Source mode. In order to minimize the skew it is recommended to use the same clock distribution device such as Texas Instruments CDCE62005 to provide the DACCLK and OSTR signals to all the DAC3484 devices in the system. Swap the polarity of the DACCLK outputs with respect to the OSTR ones to establish proper phase relationship.

(4) SYNC is required to synchronize the PLL circuit in mulitple devices. The SYNC signal must meet the timing relationship with respect to the reference clock (DACCLKP/N) of the on-chip PLL circuit.

(1) Measured single ended into 50 Ω load.
(2) 4:1 transformer output termination, 50 Ω doubly terminated load
(3) Single carrier, W-CDMA with 3.84 MHz BW, 5-MHz spacing, centered at IF, PAR = 12dB. TESTMODEL 1, 10 ms

PRODUCT PREVIEW

DEFINITION OF SPECIFICATIONS

Adjacent Carrier Leakage Ratio (ACLR): Defined for a 3.84Mcps 3GPP W-CDMA input signal measured in a 3.84MHz bandwidth at a 5MHz offset from the carrier with a 12dB peak-to-average ratio.

Analog and Digital Power Supply Rejection Ratio (APSSR, DPSSR): Defined as the percentage error in the ratio of the delta IOUT and delta supply voltage normalized with respect to the ideal IOUT current.

Differential Nonlinearity (DNL): Defined as the variation in analog output associated with an ideal 1 LSB change in the digital input code.

Gain Drift: Defined as the maximum change in gain, in terms of ppm of full-scale range (FSR) per °C, from the value at ambient (25°C) to values over the full operating temperature range.

Gain Error: Defined as the percentage error (in FSR%) for the ratio between the measured full-scale output current and the ideal full-scale output current.

Integral Nonlinearity (INL): Defined as the maximum deviation of the actual analog output from the ideal output, determined by a straight line drawn from zero scale to full scale.

Intermodulation Distortion (IMD3): The two-tone IMD3 is defined as the ratio (in dBc) of the 3rd-order intermodulation distortion product to either fundamental output tone.

Offset Drift: Defined as the maximum change in DC offset, in terms of ppm of full-scale range (FSR) per °C, from the value at ambient (25°C) to values over the full operating temperature range.

Offset Error: Defined as the percentage error (in FSR%) for the ratio between the measured mid-scale output current and the ideal mid-scale output current.

Output Compliance Range: Defined as the minimum and maximum allowable voltage at the output of the current-output DAC. Exceeding this limit may result reduced reliability of the device or adversely affecting distortion performance.

Reference Voltage Drift: Defined as the maximum change of the reference voltage in ppm per degree Celsius from value at ambient (25°C) to values over the full operating temperature range.

Spurious Free Dynamic Range (SFDR): Defined as the difference (in dBc) between the peak amplitude of the output signal and the peak spurious signal within the first Nyquist zone.

Noise Spectral Density (NSD): Defined as the difference of power (indBc) between the output tone signal power and the noise floor of 1Hz bandwidth within the first Nyquist zone.

SERIAL INTERFACE

The serial port of the DAC3484 is a flexible serial interface which communicates with industry standard microprocessors and microcontrollers. The interface provides read/write access to all registers used to define the operating modes of DAC3484. It is compatible with most synchronous transfer formats and can be configured as a 3 or 4 pin interface by *sif4_ena* in register *config2*. In both configurations, SCLK is the serial interface input clock and SDENB is serial interface enable. For 3 pin configuration, SDIO is a bidirectional pin for both data in and data out. For 4 pin configuration, SDIO is bidirectional and SDO is data out only. Data is input into the device with the rising edge of SCLK. Data is output from the device on the falling edge of SCLK.

Each read/write operation is framed by signal SDENB (Serial Data Enable Bar) asserted low. The first frame byte is the instruction cycle which identifies the following data transfer cycle as read or write as well as the 7-bit address to be accessed. Table 1 indicates the function of each bit in the instruction cycle and is followed by a detailed description of each bit. The data transfer cycle consists of two bytes.

Table 1. Instruction Byte of the Serial Interface

	MSB							LSB
Bit	7	6	5	4	3	2	1	0
Description	R/W	A6	A5	A4	A3	A2	A1	A0

R/W   Identifies the following data transfer cycle as a read or write operation. A high indicates a read operation from DAC3484 and a low indicates a write operation to DAC3484.

[A6 : A0]   Identifies the address of the register to be accessed during the read or write operation.

Figure 1 shows the serial interface timing diagram for a DAC3484 write operation. SCLK is the serial interface clock input to DAC3484. Serial data enable SDENB is an active low input to DAC3484. SDIO is serial data in. Input data to DAC3484 is clocked on the rising edges of SCLK.
PRODUCT PREVIEW

Figure 1. Serial Interface Write Timing Diagram

Figure 2 shows the serial interface timing diagram for a DAC3484 read operation. SCLK is the serial interface clock input to DAC3484. Serial data enable SDENB is an active low input to DAC3484. SDIO is serial data in during the instruction cycle. In 3 pin configuration, SDIO is data out from the DAC3484 during the data transfer cycle, while SDO is in a high-impedance state. In 4 pin configuration, both SDIO and SDO are data out from the DAC3484 during the data transfer cycle. At the end of the data transfer, SDIO and SDO will output low on the final falling edge of SCLK until the rising edge of SDENB when they will 3-state.

REGISTER DESCRIPTIONS

Register name: config0 – Address: 0x00, Default: 0x049C

Register Name	Address	Bit	Name	Function	Default Value
config0	0x00	15	qmc_offsetAB_ena	When set, the digital Quadrature Modulator Correction (QMC) offset correction for the AB data path is enabled.	0
		14	qmc_offsetCD_ena	When set, the digital Quadrature Modulator Correction (QMC) offset correction for the CD data path is enabled.	0
		13	qmc_corrAB_ena	When set, the QMC phase and gain correction circuitry for the AB data path is enabled.	0
		12	qmc_corrCD_ena	When set, the QMC phase and gain correction circuitry for the CD data path is enabled.	0
		11:8	interp(3:0)	These bits define the interpolation factor <table><tr><td>**interp**</td><td>**Interpolation Factor**</td></tr><tr><td>0000</td><td>1x</td></tr><tr><td>0001</td><td>2x</td></tr><tr><td>0010</td><td>4x</td></tr><tr><td>0100</td><td>8x</td></tr><tr><td>1000</td><td>16x</td></tr></table>	0100
		7	fifo_ena	When set, the FIFO is enabled. **When the FIFO is disabled DACCCLKP/N and DATACLKP/N must be aligned to within $t_{(align)}$ (not recommended).**	1
		6	Reserved	Reserved for factory use.	0
		5	Reserved	Reserved for factory use.	0
		4	alarm_out_ena	When set, the ALARM pin becomes an output. When cleared, the ALARM pin is 3-stated.	1

		3	alarm_out_pol	This bit changes the polarity of the ALARM signal.
				    0: Negative logic
				    1: Positive logic
					1

		2	clkdiv_sync_ena	When set, enables the syncing of the clock divider using the sync source selected by register *config19*. The internal divided-down clocks will be phase aligned after syncing. Setting to "0" after the DAC is initialized is recommended.	1
		1	invsincAB_ena	When set, the inverse sinc filter for the AB data is enabled.	0
		0	invsincCD_ena	When set, the inverse sinc filter for the CD data is enabled.	0

Register name: config1 – Address: 0x01, Default: 0x050E

Register Name	Address	Bit	Name	Function	Default Value
config1	0x01	15	iotest_ena	When set, enables the data pattern checker test. ***The outputs are deactivated regardless of the state of TXENABLE and sif_txenable.***	0
		14	Reserved	Reserved for factory use.	0
		13	Reserved	Reserved for factory use.	0
		12	64cnt_ena	When set, enables resetting of the alarms after 64 good samples with the goal of removing unnecessary errors. For instance, when checking setup/hold through the pattern checker test, there may initially be errors. Setting this bit removes the need for a SIF write to clear the alarm register.	0
		11	oddeven_parity	Selects between odd and even parity check 0: Even parity 1: Odd parity	0
		10	word_parity_ena	When set, enables parity checking of each input word using the PARITYP/N parity input. It should match the **oddeven_parity** register setting.	1
		9	frame_parity_ena	When set, enables parity checking using the FRAME signal to source the parity bit.	0
		8	Reserved	Reserved for factory use.	1
		7	dacA_complement	When set, the DACA output is complemented. This allows to effectively change the + and – designations of the LVDS data lines.	0
		6	dacB_complement	When set, the DACB output is complemented. This allows to effectively change the + and – designations of the LVDS data lines.	0
		5	dacC_complement	When set, the DACC output is complemented. This allows to effectively change the + and – designations of the LVDS data lines.	0
		4	dacD_complement	When set, the DACD output is complemented. This allows to effectively change the + and – designations of the LVDS data lines.	0
		3	alarm_2away_ena	When set, the alarm from the FIFO indicating the write and read pointers being 2 away is enabled.	1
		2	alarm_1away_ena	When set, the alarm from the FIFO indicating the write and read pointers being 1 away is enabled.	1
		1	alarm_collision_ena	When set, the alarm from the FIFO indicating a collision between the write and read pointers is enabled.	1
		0	Reserved	Reserved for factory use.	0

PRODUCT PREVIEW

Register name: config2 – Address: 0x02, Default: 0x7000

Register Name	Address	Bit	Name	Function	Default Value
config2	0x02	15	16bit_in	When set, the input interface is set to word-wide mode. When cleared, the input interface is set to byte-wide mode.	0
		14	dacclkgone_ena	When set, the DACCLK-gone signal from the clock monitor circuit can be used to shut off the DAC outputs.	1
		13	dataclkgone_ena	When set, the DATACLK-gone signal from the clock monitor circuit can be used to shut off the DAC outputs.	1
		12	collisiongone_ena	When set, the FIFO collision alarms can be used to shut off the DAC outputs.	1
		11	clkmonsync_ena	When set, the clock monitor circuit is synced with every rising edge of the syncs chosen for the FIFO read and write pointers. See config32.	0
		10	Reserved	Reserved for factory use.	0
		9	Reserved	Reserved for factory use.	0
		8	Reserved	Reserved for factory use.	0
		7	sif4_ena	When set, the serial interface (SIF) is a 4 bit interface, otherwise it is a 3 bit interface.	0
		6	mixer_ena	When set, the mixer block is enabled.	0
		5	mixer_gain	When set, a 6dB gain is added to the mixer output.	0
		4	nco_ena	When set, the NCO is enabled. This is not required for coarse mixing.	0
		3	revbus	When set, the input bits for the data bus are reversed. MSB becomes LSB.	0
		2	Reserved	Reserved for factory use.	0
		1	twos	When set, the input data format is expected to be 2's complement. When cleared, the input is expected to be offset-binary.	0
		0	Reserved	Reserved for factory use.	0

Register name: config3 – Address: 0x03, Default: 0xF000

Register Name	Address	Bit	Name	Function	Default Value
config3	0x03	15:12	coarse_dac(3:0)	Scales the output current in 16 equal steps. $$I_{FS} = \frac{V_{EXTIO}}{R_{BIAS}} \times 2 \times (coarse\_dac + 1)$$	1111
		11:8	Reserved	Reserved for factory use.	0000
		7:1	Reserved	Reserved for factory use.	0000000
		0	sif_txenable	When set, the internal value of TXENABLE is set to "1". To enable analog output data transmission, set *sif_txenable* to "1" **or** pull CMOS TXENABLE pin (A32) to high. To disable analog output, set *sif_txenable* to "0" **and** pull CMOS TXENABLE pin (A32) to low.	0

Register name: config4 – Address: 0x04, Default: No RESET Value (WRITE TO CLEAR)

Register Name	Address	Bit	Name	Function	Default Value
config4	0x04	15:0	iotest_results(15:0)	This register is used with pattern checker test enabled (*iotest_ena* in *config1*, *bit<15>* set to "1"). It does not have a default RESET value. The values of these bits tell which bit in the word failed during the pattern checker test. iotest_results(15:8) correspond to the data bits on D[15:8] and iotest_results(7:0) correspond to the data bits on D[7:0].	No RESET Value

PRODUCT PREVIEW

Register name: config5 – Address: 0x05, Default: 0x0000 (WRITE TO CLEAR)

Register Name	Address	Bit	Name	Function	Default Value
config5	0x05	15	alarm_from_zerochk	Alarm indicating the FIFO write pointer has an all zeros pattern in it. Since this pointer is a shift register, all zeros will cause the input point to be stuck until the next sync. This alarm allows checking for this condition. This alarm indicates that another sync is necessary to restart the FIFO pointer.	0
		14	Reserved	Reserved for factory use.	0

		13:11	alarms_from_fifo(2:0)	Alarm indicating FIFO pointer collisions and nearness:
				    000: All fine
				    001: Pointers are 2 away
				    01x: Pointers are 1 away
				    1xx: FIFO pointer collision
				If the FIFO pointer collision alarm is set when *collisiongone_ena* is enabled, the FIFO must be re-synchronized and the bits must be cleared to resume normal operation.
					000

		10	alarm_dacclk_gone	Alarm indicating the DACCLK has been stopped. If the bit is set when *dacclkgone_ena* is enabled, the DACCLK must resume and the bit must be cleared to resume normal operation.	0
		9	alarm_dataclk_gone	Alarm indicating the DATACLK has been stopped. If the bit is set when dataclkgone_ena is enabled, the DATACLK must resume and the bit must be cleared to resume normal operation.	0
		8	clock_gone	Alarm indicating either *alarm_daclk_gone* or *alarm_dataclk_gone* are asserted. It controls the output. When high it will output "0x8000" for each output connected to the DAC. If the bit is set when *dacclkgone_ena* and/or *dataclkgone_ena* are enabled, the DACCLK and/or the DATACLK must resume and the bit must be cleared to resume normal operation.	0
		7	alarm_from_iotest	Alarm indicating the input data pattern does not match the pattern in the iotest_pattern registers.	0
		6	Reserved	Reserved for factory use.	0
		5	alarm_from_pll	Alarm indicating the PLL has lost lock.	0
		4	alarm_rparity	Alarm indicating a parity error on data captured on the rising edge of DATACLKP/N.	0
		3	alarm_fparity	Alarm indicating a parity error on data captured on the falling edge of DATACLKP/N.	0
		2	alarm_frame_parity	Alarm indicating a parity error when using the FRAME as parity bit.	0
		1	Reserved	Reserved for factory use.	0
		0	Reserved	Reserved for factory use.	0

Register name: config6 – Address: 0x06, Default: No RESET Value (READ ONLY)

Register Name	Address	Bit	Name	Function	Default Value
config6	0x06	15:8	tempdata(7:0)	This is the output from the chip temperature sensor. The value of this register in two's complement format represents the temperature in degrees Celsius. **This register must be read with a minimum SCLK period of 1μs.**	No RESET Value
		7:2	Reserved	Reserved for factory use.	000000
		1	Reserved	Reserved for factory use.	0

PRODUCT PREVIEW

DATA INTERFACE

The DAC3484 has a 16-bit LVDS bus that accepts quad, 16-bit data either in word-wide or dual byte-wide formats. The quad, 16-bit data can be input to the device using either a single-bus, 16-bit interface or a dual-bus, 8-bit interface. The selection between the two modes is done through *16bit_in* in the *config2* register. The LVDS bus inputs in each mode are shown in Table 3.

Table 3. LVDS Bus Input Assignment

Input Mode	Pins
Word-wide	D[15..0] → Data for paths A, B, C and D
Byte-wide	D[15..8] → Data for paths A and B D[7..0] → Data for paths C and D

Data is sampled by the LVDS double data rate (DDR) clock DATACLK. Setup and hold requirements must be met for proper sampling.

For both input bus modes, a sync signal, either FRAME or SYNC, is required to sync the FIFO read and/or write pointers. In byte-wide mode the sync source is also used to establish the correct sample boundaries.

The sync signal, either FRAME or SYNC, can be either a pulse or a periodic signal where the sync period corresponds to multiples of 8 samples. FRAME or SYNC is sampled by a rising edge in DATACLK. The pulse-width (T_{FRAME_SYNC}) needs to be at least equal to 1/2 of the DATACLK period.

For both input bus mode, the value in FRAME sampled by the next falling edge in DATACLK can be used as a block parity value. This feature is enabled by setting *frame_parity_ena* in register *config1* to "1". Refer to "Parity Check Test" section for more detail

WORD-WIDE FORMAT

The single-bus, 16-bit interface is selected by setting *16bin_in* to "1" in the *config2* register. In this mode the 16-bit data for channels A, B, C and D is input word-wide interleaved in the form A_0, B_0, C_0, D_0, A*1*… into the D[15:0]P/N LVDS bus. Data into the DAC3484 is formatted according to the diagram shown in Figure 3 where index 0 is the data LSB and index 15 is the data MSB.
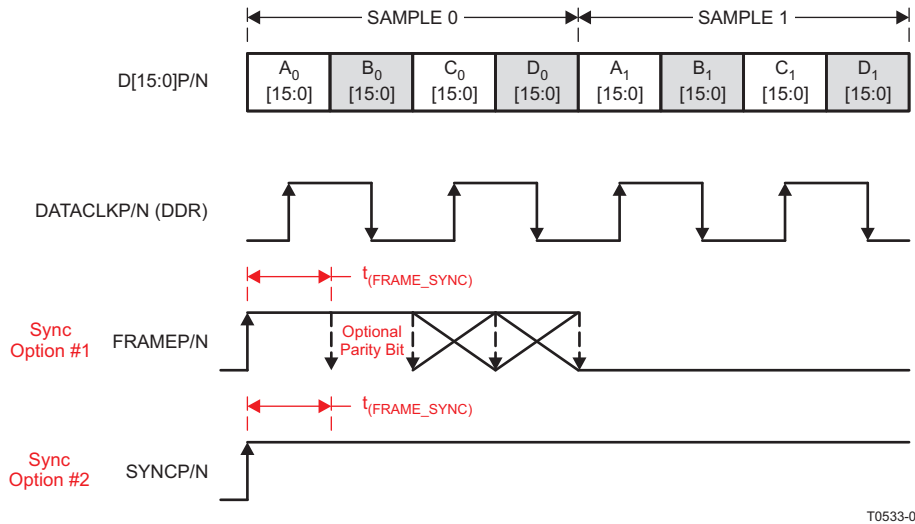

Figure 3. Word-wide Data Transmission Format

Product Folder Link(s): *DAC3484*

BYTE-WIDE FORMAT

The dual-bus, 8-bit interface is selected by setting *16bin_in* to "0" in the *config2* register. In this mode the 16-bit data for channels A and B is interleaved in the form $A_0[15:8]$, $A_0[7:0]$, $B_0[15:8]$, $B_0[7:0]$, $A_1[15:8]$… into the D[15:8]P/N LVDS inputs. Similarly data for channels C and D is interleaved into the D[7:0]P/N LVDS inputs. Data into the DAC3484 is formatted according to the diagram shown in Figure 4 where index 0 is the data LSB and index 15 is the data MSB.
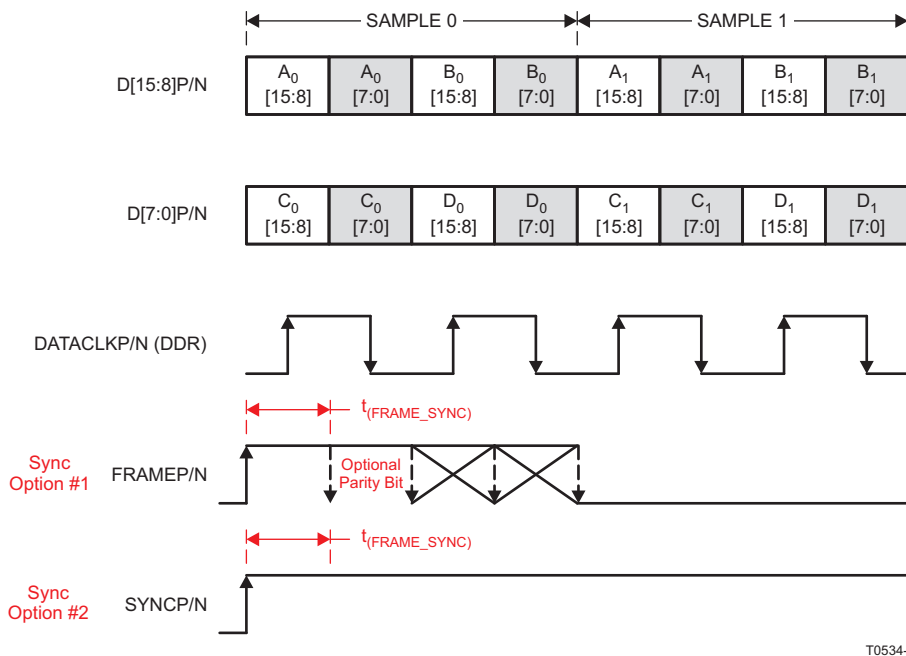

Figure 4. Byte-wide Data Transmission Format

INPUT FIFO

The DAC3484 includes a 4-channel, 16-bits wide and 8-samples deep input FIFO which acts as an elastic buffer. The purpose of the FIFO is to absorb any timing variations between the input data and the internal DAC data rate clock such as the ones resulting from clock-to-data variations from the data source.

Figure 5 shows a simplified block diagram of the FIFO.

PRODUCT PREVIEW

TEXAS INSTRUMENTS
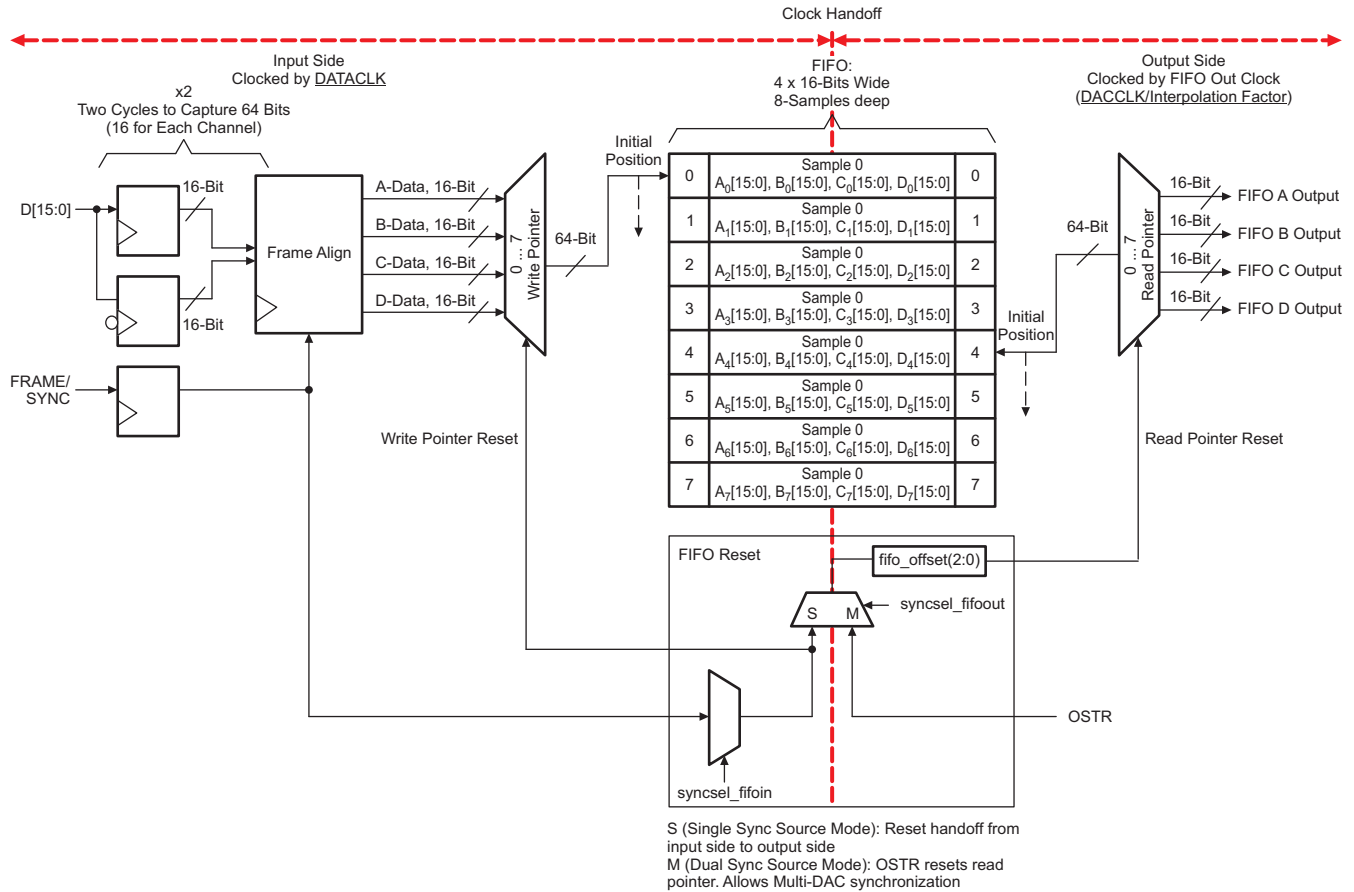

Figure 5. DAC3484 FIFO Block Diagram

Data is written to the device 16-bits at a time on the rising and falling edges of DATACLK. In order to form a complete 64-bit wide sample (16-bit A-data, 16-bit B-data, 16-bit C-data, and 16-bit D-data) two DATACLK periods are required. Each 64-bit wide sample is written into the FIFO at the address indicated by the write pointer. Similarly, data from the FIFO is read by the FIFO Out Clock 64-bits at a time from the address indicated by the read pointer. The FIFO Out Clock is generated internally from the DACCLK signal and its rate is equal to DACCLK/Interpolation. Each time a FIFO write or FIFO read is done the corresponding pointer moves to the next address.

The reset position for the FIFO read and write pointers is set by default to addresses 0 and 4 as shown in Figure 5. This offset gives optimal margin within the FIFO. The default read pointer location can be set to another value using *fifo_offset(2:0)* in register *config3* (address 4 by default). Under normal conditions data is written-to and read-from the FIFO at the same rate and consequently the write and read pointer gap remains constant. If the FIFO write and read rates are different, the corresponding pointers will be cycling at different speeds which could result in pointer collision. Under this condition the FIFO attempts to read and write data from the same address at the same time which will result in errors and thus must be avoided.

The write pointer sync source is selected by *syncsel_fifoin(4:0)* in register *config32*. In most applications either FRAME or SYNC are used to reset the write pointer. Unlike DATA, the sync signal is latched only on the rising edges of DATACLK. A rising edge on the sync signal source causes the pointer to return to its original position.

Similarly, the read pointer sync source is selected by *syncsel_fifoout(4:0)*. The write pointer sync source can be set to reset the read pointer as well. In this case, the read pointer is reset by an internal signal generated by recapturing the write pointer sync signal by the FIFO Out clock. This clock domain transfer (DATACLK to FIFO Out Clock) results in phase ambiguity of the reset signal. This limits the precise control of the output timing and makes full synchronization of multiple devices difficult.

PRODUCT PREVIEW

To alleviate this, the device offers the alternative of resetting the FIFO read pointer independently of the write pointer by using the OSTR signal. The OSTR signal is sampled by DACCLK and must satisfy the timing requirements in the specifications table. In order to minimize the skew it is recommended to use the same clock distribution device such as Texas Instruments CDCE62005 to provide the DACCLK and OSTR signals to all the DAC3484 devices in the system. Swapping the polarity of the DACCLK outputs with respect to the OSTR ones establishes proper phase relationship.

The FIFO pointers reset procedure can be done periodically or only once during initialization as the pointers automatically return to the initial position when the FIFO has been filled. To reset the FIFO periodically, it is necessary to have the FRAME, SYNC, and OSTR signals to repeat at multiples of 8 FIFO samples. To disable FIFO reset, set *syncsel_fifoin(4:0)* and *syncsel_fifoout(4:0)* to "0000".

The frequency limitation for FRAME and SYNC signals are the following:

$f_{sync} = f_{DATACLK}/(n \times 16)$ where n = 1, 2, … for Word-Wide and Byte-Wide Mode

The frequency limitation for the OSTR signal is the following:

$f_{OSTR} = f_{DAC}/(n \times \text{interpolation} \times 8)$ where n = 1, 2, …

The frequencies above are at maximum when n = 1. This is when the FRAME, SYNC, or OSTR have a rising edge transition every 8 FIFO samples. The occurrence can be made less frequent by setting n > 1, for example, every n × 8 FIFO samples.
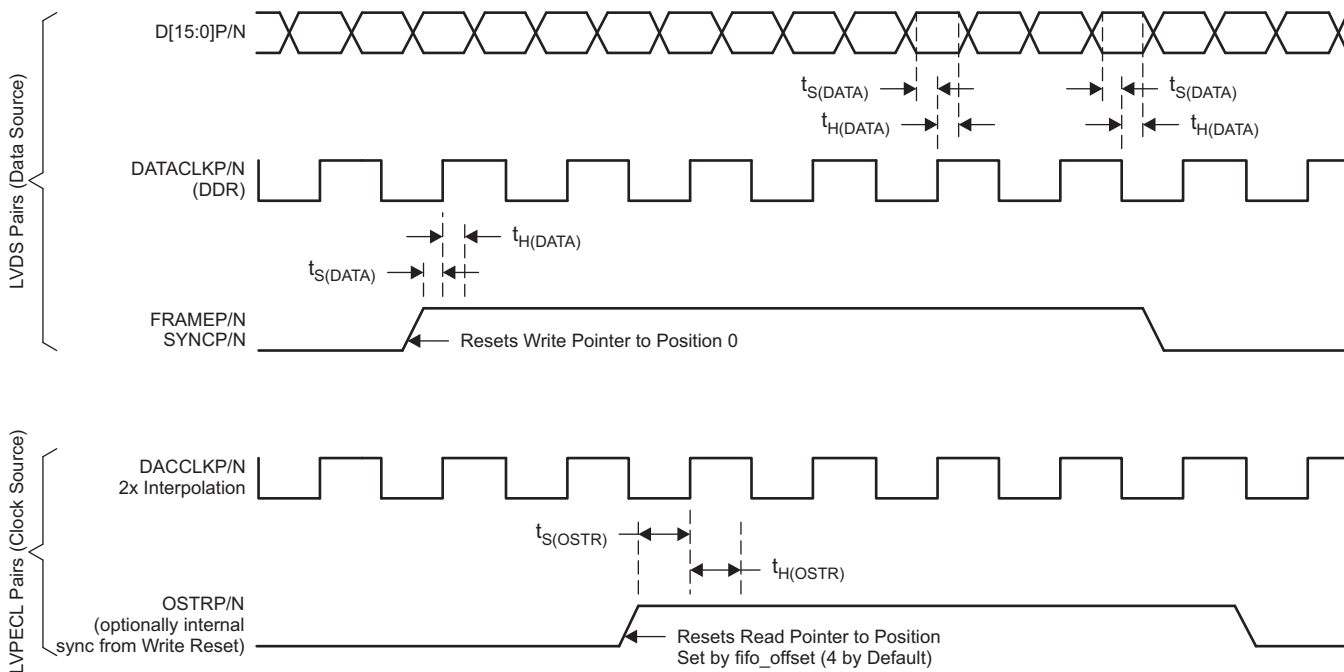

Figure 6. FIFO Write and Read Descriptions

FIFO MODES OF OPERATION

The DAC3484 input FIFO can be completely bypassed through registers *config1* and *config32*. The register configuration for each mode is described in Table 4.

Register	Control Bits
config1	fifo_ena
config32	syncsel_fifoout(4:0)

Table 4. FIFO Operation Modes

FIFO Mode	config1 and config32 FIFO Bits				
	fifo_ena	syncsel_fifoout			
		Bit 3: sif_sync	Bit 2: OSTR	Bit 1: FRAME	Bit 0: SYNC
Dual Sync Source	1	0	1	0	0
Single Sync Source	1	0	0	1 or 0 Depends on the sync source	1 or 0 Depends on the sync source
Bypass	0	X	X	X	X

DUAL SYNC SOURCE MODE

This is the recommended mode of operation for those applications that require precise control of the output timing. In Dual Sync Source mode, the FIFO write and read pointers are reset independently. The FIFO write pointer is reset using the LVDS FRAME or SYNC signal, and the FIFO read pointer is reset using the LVPECL OSTR signal. This allows LVPECL OSTR signal to control the phase of the output for either a single chip or multiple chips. Multiple devices can be fully synchronized in this mode.

SINGLE SYNC SOURCE MODE

In Single Sync Source mode, the FIFO write and read pointers are reset from the same source, either LVDS FRAME or LVDS SYNC signal. This mode has a possibility of up to 2 DAC clocks offset between the multiple DAC outputs. Applications requiring exact output timing control will need Dual Sync Source mode instead of Single Sync Source Mode.

BYPASS MODE

In FIFO bypass mode, the FIFO block is not used. As a result the input data is handed off from the DATACLK to the DACCLK domain without any compensation. In this mode the relationship between DATACLK and DACCLK $t_{(align)}$ is critical and used as a synchronizing mechanism for the internal logic. Due to the $t_{(align)}$ constraint this mode is *not recommended*. In bypass mode the pointers have no effect on the data path or handoff.

CLOCKING MODES

The DAC3484 has a dual clock setup in which a DAC clock signal is used to clock the DAC cores and internal digital logic and a separate DATA clock is used to clock the input LVDS receivers and FIFO input. The DAC34824 DAC clock signal can be sourced directly or generated through an on-chip low-jitter phase-locked loop (PLL).

In those applications requiring extremely low noise it is recommended to bypass the PLL and source the DAC clock directly from a high-quality external clock to the DACCLK input. In most applications system clocking can be simplified by using the on-chip PLL to generate the DAC core clock while still satisfying performance requirements. In this case the DACCLK pins are used as the reference frequency input to the PLL.
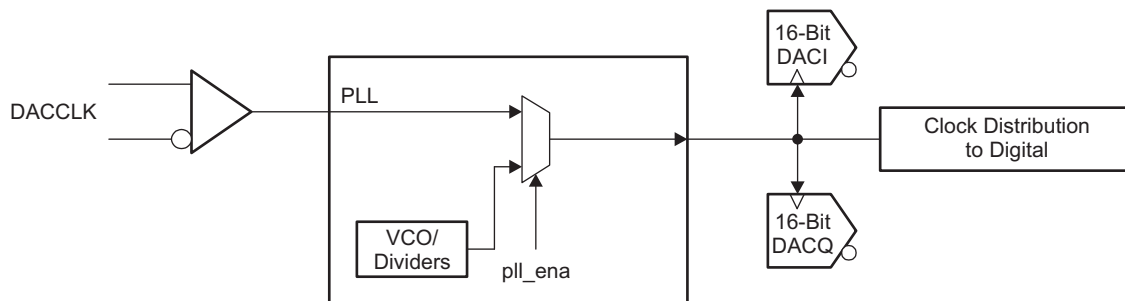

B0452-01

Figure 7. Top Level Clock Diagram

PLL BYPASS MODE

In PLL bypass mode a very high quality clock is sourced to the DACCLK inputs. This clock is used to directly clock the DAC3484 DAC cores. This mode gives the device best performance and is recommended for extremely demanding applications.

The bypass mode is selected by setting the following:
 1. *pll_ena* bit in register *config24* to "0" to bypass the PLL circuitry.
 2. *pll_sleep* bit in register *config24* to "1" to put the PLL and VCO into sleep mode.

PLL MODE

In this mode the clock at the DACCLK input functions as a reference clock source to the on-chip PLL. The on-chip PLL will then multiply this reference clock to supply a higher frequency DAC cores clock. Figure 8 shows the block diagram of the PLL circuit.

Note:
The PLL generates internal OSTR signal. In this mode external LVPECL OSTR signal is not required.

If the DAC is configured with PLL enabled with Dual Sync Source mode, then the PFD frequency has to be the pre-defined OSTR frequency.
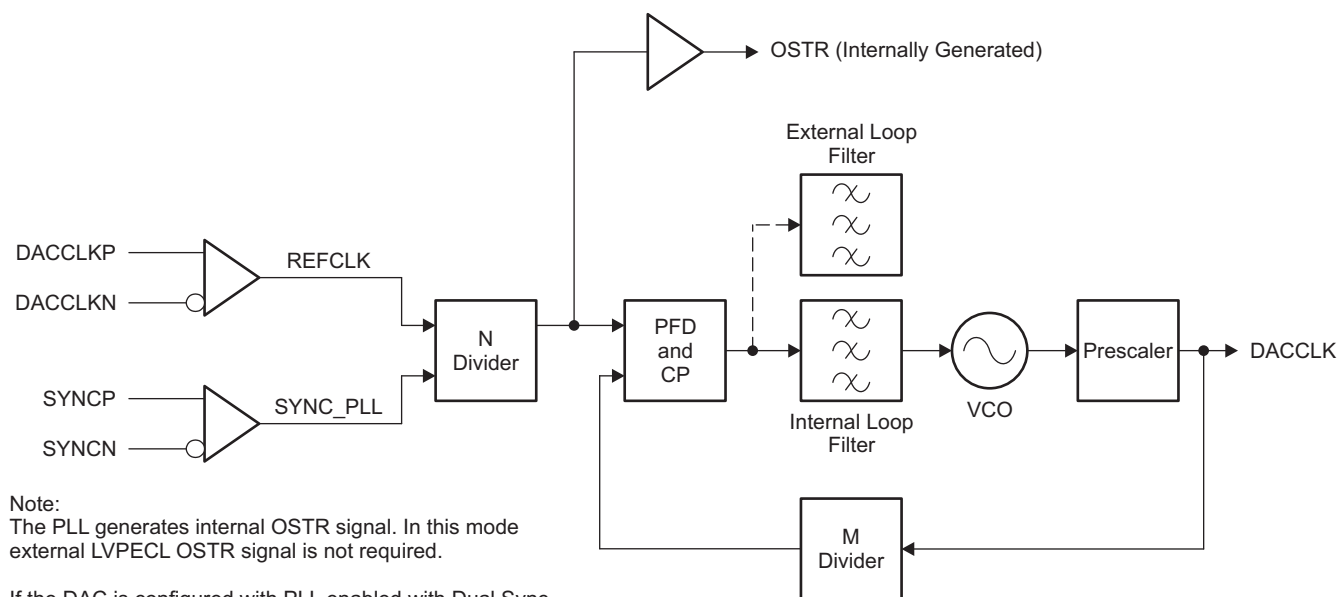

B0453-01

Figure 8. PLL Block Diagram

The DAC3484 PLL mode is selected by setting the following:
 1. *pll_ena* bit in register *config24* to "1" to route to the PLL clock path.
 2. *pll_sleep* bit in register *config24* to "0" to enable the PLL and VCO.

The output frequency of the VCO is designed to be the in the range from 3.3GHz to 4.0GHz. This VCO range is tuned to a target of 3.6864GHz but can be further adjusted by using the 6-bits *pll_vco* in register *config26*.

PRODUCT PREVIEW
Figure 9. Typical PLL/VCO Lock Range vs Coarse Tuning Bits

Common wireless infrastructure frequencies (614.4MHz, 737.28MHz, 1.2288GHz, etc.) are generated from this VCO frequency in conjunction with the pre-scaler setting *pll_p* in register *config24* as shown in Table 6.

Table 5. VCO Operation

VCO Frequency (MHz)	Pre-Scale Divider	Desired DACCLK (MHz)	pll_p(2:0)
3440.64	7	491.52	111
3686.4	6	614.4	110
3686.4	5	737.28	101
3686.4	3	1228.8	011

The M divider is used to determine the phase-frequency-detector (PFD) and charge-pump (CP) frequency.

Table 6. PFD and CP Operation

DACCLK Frequency (MHz)	M Divider	PDF Update Rate (MHz)	pll_m(7:0)
491.52	4	122.88	00000100
491.52	8	61.44	00001000
491.52	16	30.72	00010000
491.52	32	15.36	00100000

The N divider in the loop allows the PFD to operate at a lower frequency than the reference clock.

The overall divide ratio inside the loop is the product of the Pre-Scale and M dividers (P * M) and the following guidelines should be followed:

• The overall divide ratio range is from 24 to 480
• When the overall divide ratio is less than 120, the internal loop filter can guarantee a stable loop
• When the overall divide ratio is greater than 120, either an external loop filter or a double charge pump setting are required to ensure loop stability

The single and double charge pump current options are selected by setting *pll_cp* in register *config24* to "01" and "11" respectively. When using the double charge pump setting an external loop filter is not required.

If an external filter is required, the following filter should be connected to the LPF pin (A1):
Figure 10. Recommended External Loop Filter

The PLL generates an internal OSTR signal and does not require the external LVPECL OSTR signal. The OSTR signal is buffered from the N-divider output in the PLL block, and the frequency of the signal is the same as the PFD frequency. Therefore, using PLL with Dual Sync Source mode would require the PFD frequency to be the pre-defined OSTR frequency. This will allow the FIFO to be synced correctly by the internal OSTR.

MULTI-DEVICE SYNCHRONIZATION

In various applications, such as multi antenna systems where the various transmit channels information is correlated, it is required that multiple DAC devices are completely synchronized such that their outputs are phase aligned. The DAC3484 architecture supports this mode of operation.

MULTI-DEVICE SYNCHRONIZATION: PLL BYPASSED WITH DUAL SYNC SOURCE MODE

For single or multi-device synchronization it is important that delay differences in the data are absorbed by the device so that latency through the device remains the same. Furthermore, to guarantee that the outputs from each DAC are phase aligned it is necessary that data is read from the FIFO of each device simultaneously. In the DAC3484 this is accomplished by operating the multiple devices in Dual Sync Source mode. In this mode the additional OSTR signal is required by each DAC3484 to be synchronized.

Data into the device is input as LVDS signals from one or multiple baseband ASICs or FPGAs. Data into the multiple DAC devices can experience different delays due to variations in the digital source output paths or board level wiring. These different delays can be effectively absorbed by the DAC3484 FIFO so that all outputs are phase aligned correctly.
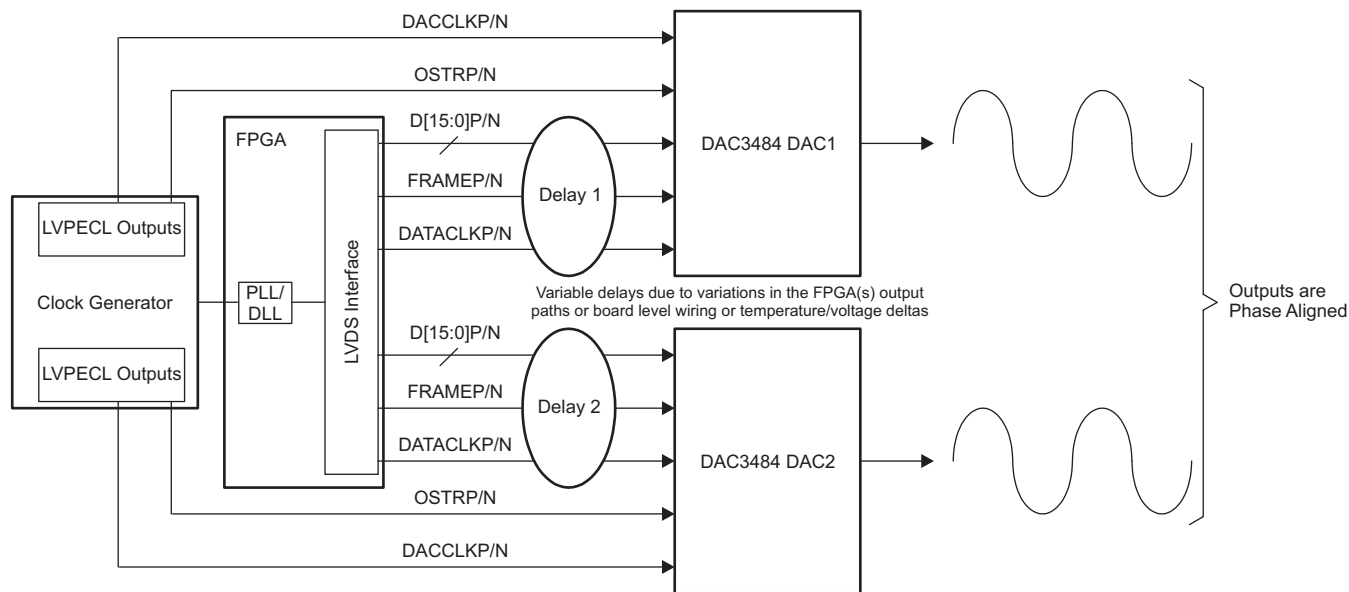

Figure 11. SynchronizationSystem in Dual Sync Source Mode with PLL Bypassed

For correct operation both OSTR and DACCLK must be generated from the same clock domain. The OSTR signal is sampled by DACCLK and must satisfy the timing requirements in the specifications table. If the clock generator does not have the ability to delay the DACCLK to meet the OSTR timing requirement, the polarity of the DACCLK outputs can be swapped with respect to the OSTR ones to create 180 degree phase delay of the DACCLK. This may help establish proper setup and hold time requirement of the OSTR signal.

Careful board layout planning must be done to ensure that the DACCLK and OSTR signals are distributed from device to device with the lowest skew possible as this will affect the synchronization process. In order to minimize the skew across devices it is recommended to use the same clock distribution device to provide the DACCLK and OSTR signals to all the DAC devices in the system.
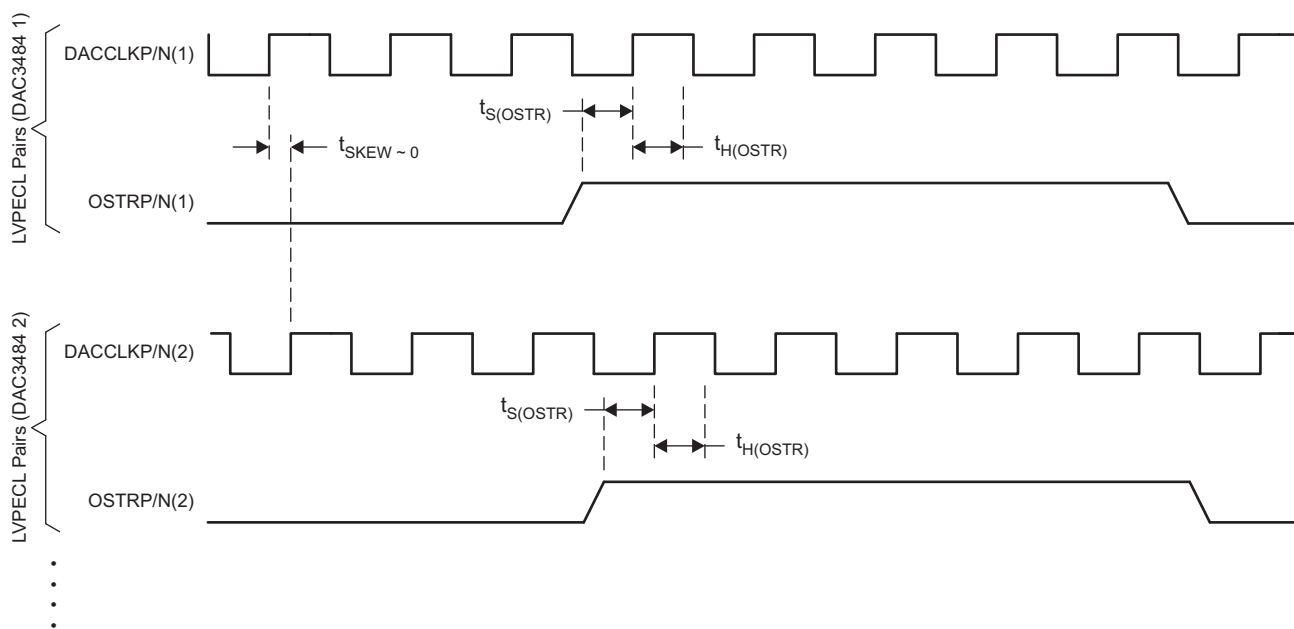

Figure 12. Timing Diagram for LVPECL Synchronization Signals

The following steps are required to ensure the devices are fully synchronized. The procedure assumes all the DAC3484 devices have a DACCLK and OSTR signal and must be carried out on each device.

1. Start-up the device as described in the power-up sequence. Set the DAC3484 in Dual Sync Source mode and select OSTR as the clock divider sync source (*clkdiv_sync_sel* in register *config32*).
2. Sync the clock divider and FIFO pointers.
3. Verify there are no FIFO alarms either through register config5 or through the ALARM pin.

After these steps all the DAC3484 outputs will be synchronized.

MULTI-DEVICE SYNCHRONIATION: PLL ENABLED WITH DUAL SYNC SOURCE MODE

The DAC3484 allows exact phase alignment between multiple devices even when operating with the internal PLL clock multiplier. In PLL clock mode, the PLL generates the DAC clock and an internal OSTR signal from the reference clock applied to the DACCLK inputs so there is no need to supply an additional LVPECL OSTR signal.

For this method to operate properly the SYNC signal should be set to reset the PLL N dividers to a known state by setting *pll_ndivsync_ena* in register *config24* to "1". The SYNC signal resets the PLL N dividers with a rising edge, and the timing relationship $t_{s(SYNC\_PLL)}$ and $t_{h(SYNC\_PLL)}$ are relative to the reference clock presented on the DACCLK pin.

Both SYNC and DACCLK can be set as low frequency signals to greatly simplifying trace routing (SYNC can be just a pulse as a single rising edge is required, if using a periodic signal it is recommended to clear the *pll_ndivsync_ena* bit after resetting the PLL dividers). Besides the $t_{s(SYNC\_PLL)}$ and $t_{h(SYNC\_PLL)}$ requirement between SYNC and DACCLK, there is no additional required timing relationship between the SYNC and FRAME signals or between DACCLK and DATACLK. The only restriction as in the PLL disabled case is that the DACCLK and SYNC signals are distributed from device to device with the lowest skew possible.
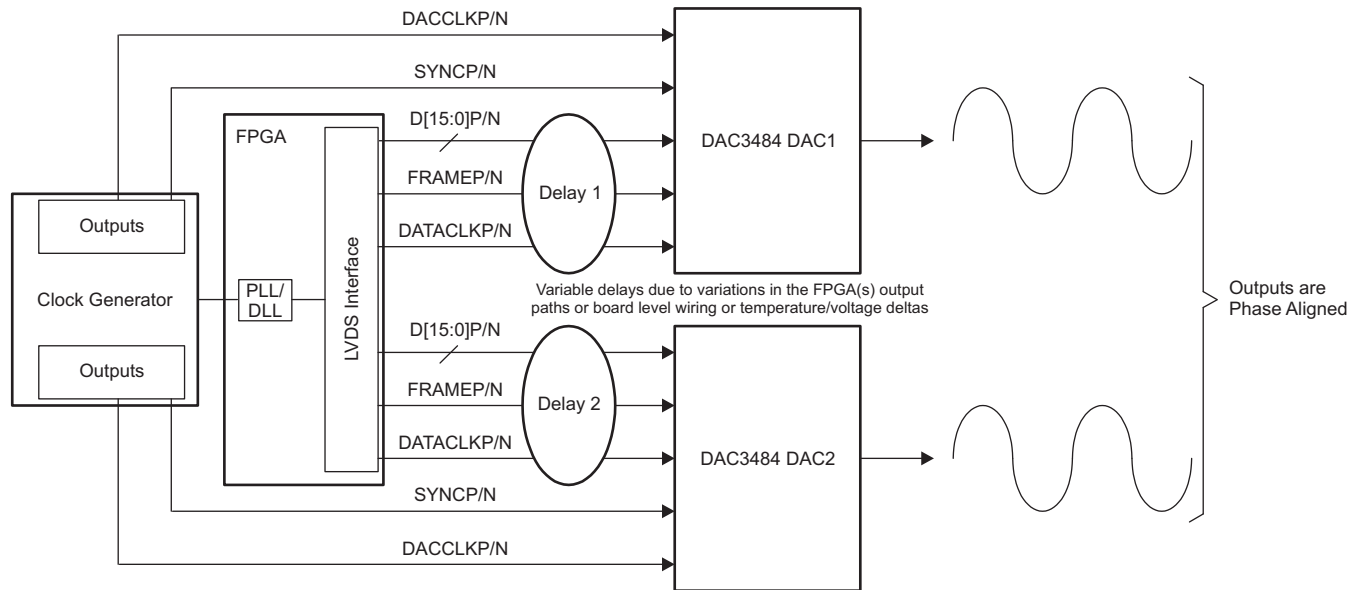

Figure 13. Synchronization System in Dual Sync Source Mode with PLL Enabled

The following steps are required to ensure the devices are fully synchronized. The procedure assumes all the DAC3484 devices have a DACCLK and SYNCH signal and the following steps must be carried out on each device.

1. Start-up the device as described in the power-up sequence. Set the DAC3484 in Dual Sync Source mode and enable SYNC to reset the PLL dividers (set *pll_ndivsync_ena* in register *config24* to "1").
2. Reset the PLL dividers with a rising edge on SYNC.
3. Disable PLL dividers resetting.
4. Sync the clock divider and FIFO pointers.
5. Verify there are no FIFO alarms either through register *config5* or through the ALARM pin.

After these steps all the DAC3484 outputs will be synchronized.

MULTI-DEVICE OPERATION: SINGLE SYNC SOURCE MODE

In Single Sync Source mode, the FIFO write and read pointers are reset from the same sync source, either FRAME or SYNC. Although the FIFO in this mode can still absorb the data delay differences due to variations in the digital source output paths or board level wiring it is impossible to guarantee data will be read from the FIFO of different devices simultaneously thus preventing exact phase alignment.

In Single Sync Source mode the FIFO read pointer reset is handoff between the two clock domains (DATACLK and FIFO OUT CLOCK) by simply re-sampling the write pointer reset. Since the two clocks are asynchronous there is a small but distinct possibility of a meta-stablility during the pointer handoff. This meta-stability can cause the outputs of the multiple devices to slip by up to 2 DAC clock cycles.

When the PLL is enabled with Single Sync Source mode, the FIFO read pointer is not synchronized by the OSTR signal. Therefore, there is no restriction on the PLL PFD frequency as described in the previous section.

FIR FILTERS

Figure 15 through Figure 18 show the magnitude spectrum response for the FIR0, FIR1, FIR2 and FIR3 interpolating filters where f_{IN} is the input data rate to the FIR filter. Figure 19 to Figure 22 show the composite filter response for 2x, 4x, 8x and 16x interpolation. The transition band for all interpolation settings is from 0.4 to 0.6 x f_{DATA} (the input data rate to the device) with <0.001dB of pass-band ripple and >90 dB stop-band attenuation.

The DAC3484 also has a 9-tap inverse sinc filter (FIR4) that runs at the DAC update rate (f_{DAC}) that can be used to flatten the frequency response of the sample-and-hold output. The DAC sample-and-hold output sets the output current and holds it constant for one DAC clock cycle until the next sample, resulting in the well-known sin(x)/x or sinc(x) frequency response (Figure 23, red line). The inverse sinc filter response (Figure 23, blue line) has the opposite frequency response from 0 to 0.4 x Fdac, resulting in the combined response (Figure 23, green line). Between 0 to 0.4 x f_{DAC}, the inverse sinc filter compensates the sample-and-hold roll-off with less than 0.03 dB error.

The inverse sinc filter has a gain >1 at all frequencies. Therefore, the signal input to FIR4 must be reduced from full scale to prevent saturation in the filter. The amount of back-off required depends on the signal frequency, and is set such that at the signal frequencies the combination of the input signal and filter response is less than 1 (0 dB). For example, if the signal input to FIR4 is at 0.25 x f_{DAC}, the response of FIR4 is 0.9 dB, and the signal must be backed off from full scale by 0.9 dB to avoid saturation. The gain function in the QMC blocks can be used to reduce the amplitude of the input signal. The advantage of FIR4 having a positive gain at all frequencies is that the user is then able to optimize the back-off of the signal based on its frequency.

The filter taps for all digital filters are listed in Table 4. Note that the loss of signal amplitude may result in lower SNR due to decrease in signal amplitude.

FULL COMPLEX MIXER

The DAC3484 has two full complex mixer (FMIX) blocks with independent Numerically Controlled Oscillators (NCO) that enables flexible frequency placement without imposing additional limitations in the signal bandwidth. The NCOs have 32-bit frequency registers (*phaseaddAB(31:0)* and *phaseaddCD(31:0)*) and 16-bit phase registers (*phaseoffsetAB(15:0)* and *phaseoffsetCD(15:0)*) that generate the sine and cosine terms for the complex mixing.

The NCO block diagram is shown below in Figure 24.

PRODUCT PREVIEW
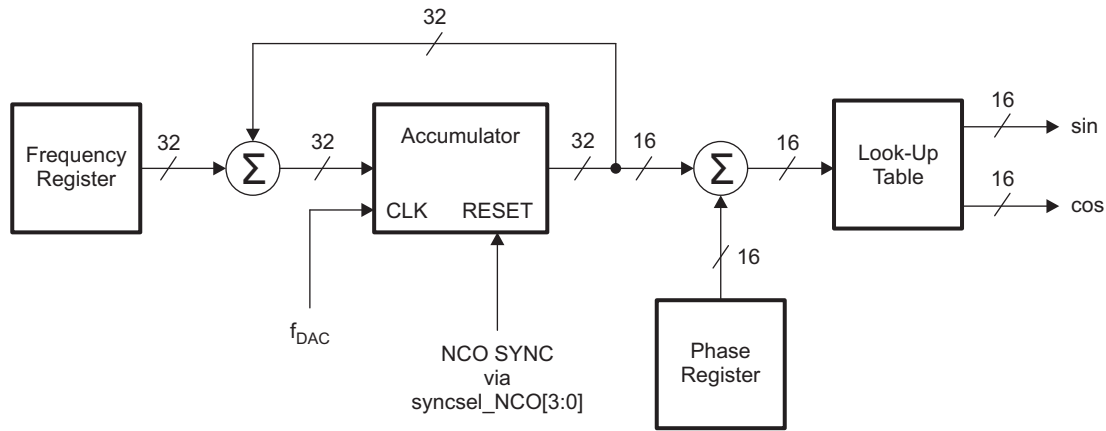

Figure 24. NCO Block Diagram

Synchronization of the NCOs occurs by resetting the NCO accumulators to zero. The synchronization source is selected by *syncsel_NCO(3:0)* in *config31*. The frequency word in the *phaseaddAB(31:0)* and *phaseaddCD(31:0)* registers is added to the accumulators every clock cycle, f_{DAC}. The output frequency of the NCO is

$$f_{NCO} = \frac{freq \times f_{NCO\_CLK}}{2^{32}}$$

(1)

Treating the two complex channels in the DAC3484 as a complex vectors of the form I + j Q, the output of FMIX $I_{OUT}(t)$ and $Q_{OUT}(t)$ is

$I_{OUT}(t) = (I_{IN}(t)\cos(2\pi f_{NCO}t + \delta) - Q_{IN}(t)\sin(2\pi f_{NCO}t + \delta)) \times 2^{(mixer\_gain - 1)}$
$Q_{OUT}(t) = (I_{IN}(t)\sin(2\pi f_{NCO}t + \delta) + Q_{IN}(t)\cos(2\pi f_{NCO}t + \delta)) \times 2^{(mixer\_gain - 1)}$

where t is the time since the last resetting of the NCO accumulator, δ is the phase offset value and *mixer_gain* is either 0 or 1. δ is given by:

δ = 2π × *phase_offsetAB/CD(15:0)*/2^{16}

The maximum output amplitude of FMIX occurs if $I_{IN}(t)$ and $Q_{IN}(t)$ are simultaneously full scale amplitude and the sine and cosine arguments are equal to 2π x $f_{NCO}t$ + δ (2N-1) × π/4 (N = 1, 2, ...).

With m*ixer_gain* = 0 in *config2*, the gain through FMIX is sqrt(2)/2 or –3 dB. This loss in signal power is in most cases undesirable, and it is recommended that the gain function of the QMC block be used to increase the signal by 3 dB to compensate. With *mixer_gain* = 1, the gain through FMIX is sqrt(2) or +3 dB, which can cause clipping of the signal if $I_{IN}(t)$ and $Q_{IN}(t)$ are simultaneously near full scale amplitude and should therefore be used with caution.

COARSE MIXER

In addition to the full complex mixer the DAC3484 also has a coarse mixer block capable of shifting the input signal spectrum by the fixed mixing frequencies ±n×f_S/8. Using the coarse mixer instead of the full mixer will result in lower power consumption.

Treating the two complex channels as a complex vector of the form I(t) + j Q(t), the outputs of the coarse mixer, $I_{OUT}(t)$ and $Q_{OUT}(t)$ are equivalent to:

$I_{OUT}(t) = I(t)\cos(2\pi f_{CMIX}t) - Q(t)\sin(2\pi f_{CMIX}t)$
$Q_{OUT}(t) = I(t)\sin(2\pi f_{CMIX}t) + Q(t)\cos(2\pi f_{CMIX}t)$

where f_{CMIX} is the fixed mixing frequency selected by *cmix(3:0)*. The mixing combinations are described in Table 8.

Table 8. Coarse Mixer Combinations

cmix(3:0)	Fs/8 Mixer cmix(3)	Fs/4 Mixer cmix(2)	Fs/2 Mixer cmix(1)	–Fs/4 Mixer cmix(0)	Mixing Mode

QUADRATURE MODULATION CORRECTION (QMC)

GAIN AND PHASE CORRECTION

The DAC3484 includes a Quadrature Modulator Correction (QMC) block. The QMC blocks provide a mean for changing the gain and phase of the complex signals to compensate for any I and Q imbalances present in an analog quadrature modulator. The block diagram for the QMC block is shown in Figure 25. The QMC block contains 3 programmable parameters.

Register *qmc_gainA/B(10:0)* and *qmc_gainC/D(10:0)* controls the I and Q path gains and is an 11-bit unsigned value with a range of 0 to 1.9990 and the default gain is 1.0000. The implied decimal point for the multiplication is between bit 9 and bit 10.

Register *qmc_phaseAB/CD(11:0)* control the phase imbalance between I and Q and is a 12-bit values with a range of –0.5 to approximately 0.49975. The QMC phase term is not a direct phase rotation but a constant that is multiplied by each "Q" sample then summed into the "I" sample path. This is an approximation of a true phase rotation in order to keep the implementation simple.

LO feed-through can be minimized by adjusting the DAC offset feature described below.

PRODUCT PREVIEW

PRODUCT PREVIEW
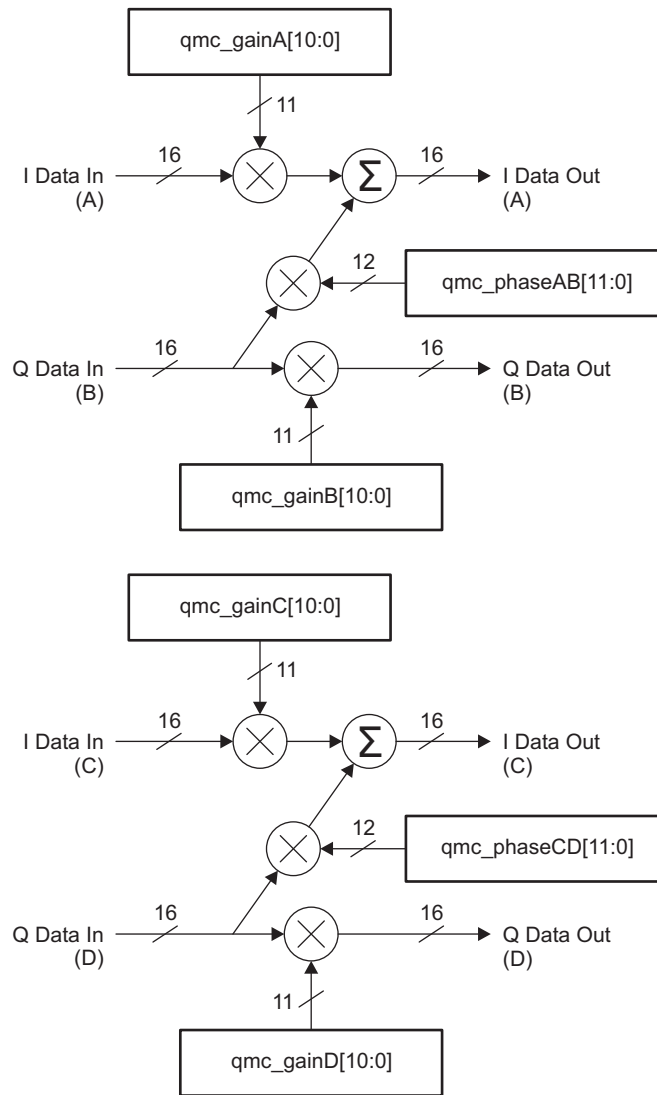

Figure 25. QMC Block Diagram

OFFSET CORRECTION

Registers *qmc_offsetA(12:0)*, *qmc_offsetB(12:0)*, *qmc_offsetC(12:0)* and *qmc_offsetD(12:0)* can be used to independently adjust the DC offsets of each channel. The offset values are in represented in 2s-complement format with a range from -4096 to 4095.

The offset value adds a digital offset to the digital data before digital-to-analog conversion. Since the offset is added directly to the data it may be necessary to back off the signal to prevent saturation. Both data and offset values are LSB aligned.
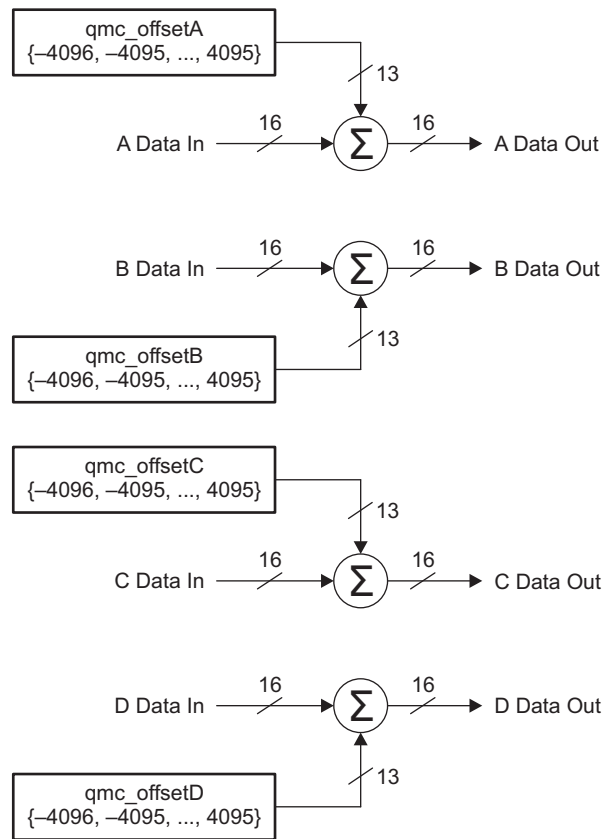

Figure 26. Digital Offset Block Diagram

GROUP DELAY CORRECTION

A complex transmitter system typically is consisted of a DAC, reconstruction filter network, and I/Q modulator. Besides the gain and phase mismatch contribution, there could also be timing mismatch contribution from each components. For instance, the timing mismatch could come from the PCB trace length variation between the I and Q channels and the group delay variation from the reconstruction filter.

This timing mismatch in the complex transmitter system creates phase mismatch that varies linearly with respect to frequency. To compensate for the I/Q imbalances due to this mismatch, the DAC3482 has group delay correction block for each DAC channel. Each DAC channel can adjust its delay through *grp_delayA(7:0)*, *grp_delayB(7:0)*, *grp_delayC(7:0)*, and *grp_delayD(7:0)* in register *config46* and *config47*. The delay range is approximately 100ps over the 256 digital steps. The group delay correction, along with gain/phase correction, can be useful for correcting imbalances in wide-band transmitter system.

TEMPERATURE SENSOR

The DAC3484 incorporates a temperature sensor block which monitors the temperature by measuring the voltage across 2 transistors. The voltage is converted to an 8-bit digital word using a successive-approximation (SAR) analog to digital conversion process. The result is scaled, limited and formatted as a twos complement value representing the temperature in degrees Celsius.

The sampling is controlled by the serial interface signals SDENB and SCLK. If the temperature sensor is enabled (*tsense_sleep* = "0" in register *config26*) a conversion takes place each time the serial port is written or read. The data is only read and sent out by the digital block when the temperature sensor is read in *tempdata(7:0)* in *config6*. The conversion uses the first eight clocks of the serial clock as the capture and conversion clock, the data is valid on the falling eighth SCLK. The data is then clocked out of the chip on the rising edge of the ninth SCLK. No other clocks to the chip are necessary for the temperature sensor operation. As a result the temperature sensor is enabled even when the device is in sleep mode.

PRODUCT PREVIEW

In order for the process described above to operate properly, the serial port read from config6 must be done with an SCLK period of at least 1 µs. If this is not satisfied the temperature sensor accuracy is greatly reduced.

DATA PATTERN CHECKER

The DAC3484 incorporates a simple pattern checker test in order to determine errors in the data interface. The main cause of failures is setup/hold timing issues. The test mode is enabled by asserting *iotest_ena* in register *config1*. In test mode the analog outputs are deactivated regardless of the state of TXENABLE or *sif_texnable* in register *config3.*

The data pattern key used for the test is 8 words long and is specified by the contents of *iotest_pattern[0:7]* in registers *config37* through *config44*. The data pattern key can be modified by changing the contents of these registers.

The first word in the test frame is determined by a rising edge transition in FRAME or SYNC, depending on the *syncsel_fifoin(4:0)* setting in *config32*. At this transition, the *pattern0* word should be input to the data pins. Patterns 1 through 7 should follow sequentially on each edge of DATACLK (rising and falling). The sequence should be repeated until the pattern checker test is disabled by setting *iotest_ena* back to "0". It is not necessary to have a rising FRAME or SYNC edge aligned with every *pattern0* word, just the first one to mark the beginning of the series.
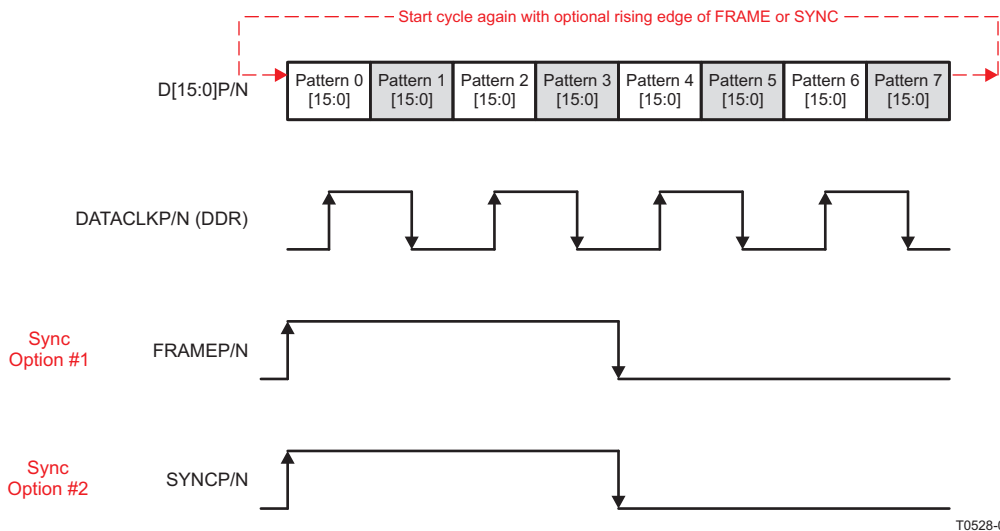

Figure 27. IO Pattern Checker Data Transmission Format

The test mode determines if the 16-bit LVDS data D[15:0]P/N of all the patterns were received correctly by comparing the received data against the data pattern key. If any of the 16-bit data D[15:0]P/N were received incorrectly, the corresponding bits in *iotest_results(15:0)* in register *config4* will be set to "1" to indicate bit error location. Furthermore, the error condition will trigger the *alarm_from_iotest* bit in register *config5* to indicate a general error in the data interface.

For instance, *pattern0* is programmed to the default of 0x7A7A. If the received Pattern 0 is 0x7A7B, then bit 0 in *iotest_results(15:0)* will be set to "1" to indicate an error in bit 0 location. The *alarm_from_iotest* will also be set to "1" to report the data transfer error. The user can then narrow down the error from the bit location information and implement the fix accordingly.

The alarms can be cleared by writing 0x0000 to *iotest_results(15:0)* and "0" to *alarm_from_iotest* through the serial interface. The serial interface will read back 0s if there are no errors or if the errors are cleared. The corresponding alarm bit will remain a "1" if the errors remain.

It is recommended to enable the pattern checker and then run the pattern sequence for 100 or more complete cycles before clearing the *iotest_results(15:0)* and *alarm_from_iotest*. This will eliminate the possibility of false alarms generated during the setup sequence.

PARITY CHECK TEST

The DAC3484 has a parity check test that enables continuous validity monitoring of the data received by the DAC. Parity check testing in combination with the data pattern checker offer an excellent solution for detecting board assembly issues due to missing pad connections.

For the parity check test, an extra parity bit is added to the data bits to ensure that the total number of set bits (bits with value 1) is even or odd. This simple scheme is used to detect single or any other odd number of data transfer errors. Parity testing is implemented in the DAC3484 in two ways: word-by-word parity and block parity.

WORD-BY-WORD PARITY

Word-by-word parity is the easiest mode to implement. In this mode the additional parity bit is sourced to the parity input (PARITYP/N) for each data word transfer into the D[15:0]P/N inputs. This mode is enabled by setting the *word_parity_ena* bit. The input parity value is defined to be the total number of logic 1s on the 17-bit data bus, the D[15:0]P/N inputs and the PARITYP/N input. This value, the total number of logic 1s, must match the parity test selected in the *oddeven_parity* bit in register *config1*.

For example, if the oddeven_parity bit is set to "1" for odd parity, then the number of 1s on the 17-bit data bus should be odd. The DAC will check the data transfer through the parity input. If the data received has odd number of 1s, then the parity is correct. If the data received has even number of 1s, then the parity is incorrect. The corresponding alarm for parity error will be set accordingly.

Figure 29 shows the simple XOR structure used to check word parity. Parity is tested independently for data captured on both rising and falling edges of DATACLK (*alarm_rparity* and *alarm_fparity*, respectively). Testing on both edges helps in determining a possible setup/hold issue. Both alarms are captured individually in register *config5*.

B0458-01

Figure 29. DAC3484 Word-by-Word Parity Check

BLOCK PARITY

The block parity method uses the FRAME signal to determine the boundaries of the data block to compute parity. This mode is enabled by setting the *frame_parity_ena* bit in register *config1*.

A low-to-high transition of FRAME captured with the DATACLK rising edge determines the end point of the parity block and the beginning of the next one. In this method the parity bit of the completed block corresponds to the FRAME value captured on the DATACLK falling edge right after the STOP/START point.

The input parity value is defined to be the total number of logic 1s in the data block. A logic HIGH captured on the falling edge of DATACLK indicates odd parity or odd number of logic 1s, while a logic LOW indicates even parity or even number of logic 1s. If the expected parity does not match the number of logic 1s in the received data, then *alarm_frame_parity* in register *config5* will be set to "1". The main advantage of the block parity mode is that there is no need for an additional parity LVDS input.

Since the FRAME signal is used for parity testing in addition to FIFO syncing and frame boundary assignment it is mandatory to take some extra steps to avoid device malfunction. If FRAME is used to reset the FIFO pointers continuosly, the block size must be a multiple of 8 samples (each sample corresponding to 16-bits A, B, C and D data). In addition since FRAME is used to establish the frame boundary, the parity block must be aligned with the data frame boundaries.
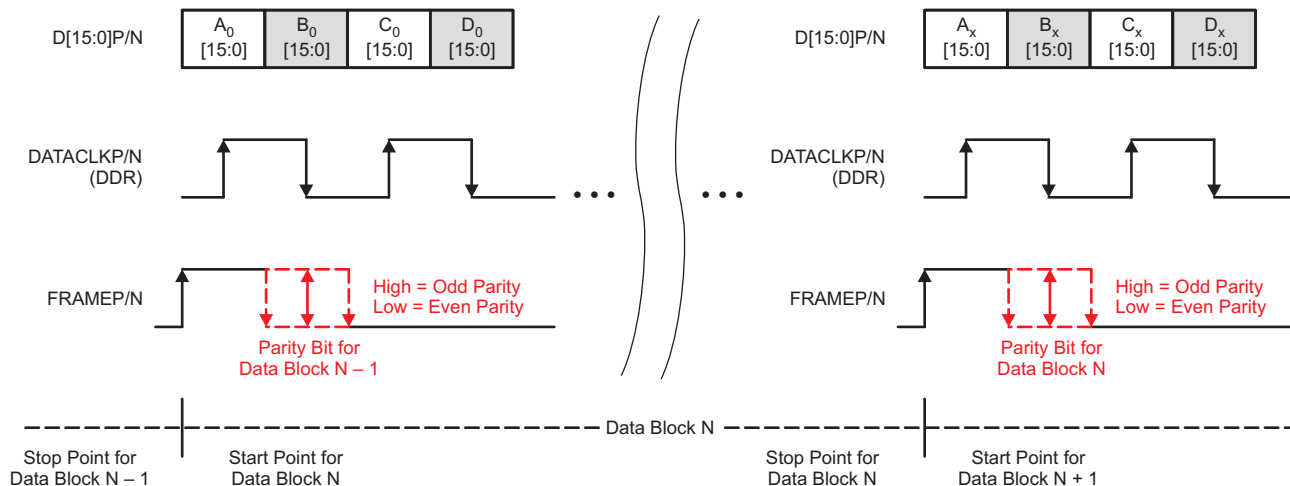

Notes: Rising edge of FRAMEP/N indicates the beginning of data block.

Parity bit for the current data block is latched on falling edge of DATACLK after the start point for next data block.

Figure 30. DAC3484 Block Parity Check (Example shown with Word Wide Mode)

DAC3484 ALARM MONITORING

The DAC3484 includes a flexible set of alarm monitoring that can be used to alert of a possible malfunction scenario. All the alarm events can be accessed either through the *config5* register or through the ALARM pin. Once an alarm is set, the corresponding alarm bit in register *config5* must be reset through the serial interface to allow further testing. The set of alarms includes the following conditions:

Zero check alarm
- *Alarm_from_zerochk*. Occurs when the FIFO write pointer has an all zeros pattern. Since the write pointer is a shift register, all zeros will cause the input point to be stuck until the next sync event. When this happens a sync to the FIFO block is required.

FIFO alarms
- *alarm_from_fifo*. Occurs when there is a collision in the FIFO pointers or a collision event is close.
  - alarm_fifo_2away. Pointers are within two addresses of each other.
  - alarm_fifo_1away. Pointers are within one address of each other.
  - alarm_fifo_collision. Pointers are equal to each other.

Clock alarms
- *clock_gone*. Occurs when either the DACCLK or DATACLOCK have been stopped.
  - alarm_dacclk_gone. Occurs when the DACCLK has been stopped.
  - alarm_dataclk_gone. Occurs when the DATACLK has been stopped.

Pattern checker alarm
- *alarm_from_iotest*. Occurs when the input data pattern does not match the pattern key.

PLL alarm
- *alarm_from_pll*. Occurs when the PLL is out of lock.

PRODUCT PREVIEW

Parity alarms

- *alarm_rparity*. Occurs when there is a parity error in the data captured by the rising edge of DATACLKP/N. The PARITYP/N input is the parity bit (word-by-word parity test).
- *alarm_fparity*. Occurs when there is a parity error in the data captured by the falling edge of DATACLKP/N. The PARITYP/N input is the parity bit (word-by-word parity test).
- *alarm_frame_parity_err*. Occurs when there is a frame parity error when using the FRAME as the parity bit (block parity test).

To prevent unexpected DAC outputs from propagating into the transmit channel chain, the clock and alarm_ fifo_collision alarms can be set in *config2* to shut-off the DAC output automatically regardless of the state of TXENABLE or *sif_txenable*.

Alarm monitoring is implemented as follows:

- Power up the device using the recommended power-up sequence.
- Clear all the alarms in *config5* by setting them to 0.
- Unmask those alarms that will generate a hardware interrupt through the ALARM pin in *config7.*
- Enable automatic DAC shut-off in register *config2* if required.
- In the case of an alarm event, the ALARM pin will trigger. If automatic DAC shut-off has been enabled the DAC outputs will be disabled.
- Read registers *config5* to determine which alarm triggered the ALARM pin.
- Correct the error condition and re-synchronize the FIFO.
- Clear the alarms in *config5.*
- Re-read *config5* to ensure the alarm event has been corrected.
- Keep clearing and reading *config5* until no error is reported.

POWER-UP SEQUENCE

The following startup sequence is recommended to power-up the DAC3484:

- Set TXENABLE low and *sif_txenable* to "0".
- Supply all 1.2V voltages (DACVDD, DIGVDD, CLKVDD and VFUSE) and all 3.3V voltages (AVDD, IOVDD, PLLAVDD and REFAVDD). The 1.2V and 3.3V supplies can be powered up simultaneously or in any order. There are no specific requirements on the ramp rate for the supplies.
- Provide all LVPECL inputs: DACCLKP/N and if used OSTRP/N.
- Toggle the RESETB pin for a minimum 25 ns active low pulse width.
- Program the SIF registers.
- Provide all LVDS inputs (D[15:0]P/N, DATACLKP/N, FRAMEP/N, SYNCP/N and PARITYP/N) simultaneously.
- Sync the clock dividers and FIFO. After a FRAMEP/N low-to-high transition, clock divider syncing must be disabled by setting *clkdiv_sync_ena* (config0, bit 2) to 0. Optionally, disable FIFO syncing by setting *syncsel_fifoin(4:0)* and *syncsel_fifoout(4:0)* to "0000" after initialization. It is recommended to sync the device FIFO only once during initialization.
- Enable transmit of data by asserting the TXENABLE pin or set *sif_txenable* to "1".

CMOS DIGITAL INPUTS

Figure 35 shows a schematic of the equivalent CMOS digital inputs of the DAC3484. SDIO, SCLK, SLEEP and TXENABLE have pull-down resistors while SDENB and RESETB have pull-up resistors internal to the DAC3484. See the specification table for logic thresholds. The pull-up and pull-down circuitry is approximately equivalent to 100kΩ.
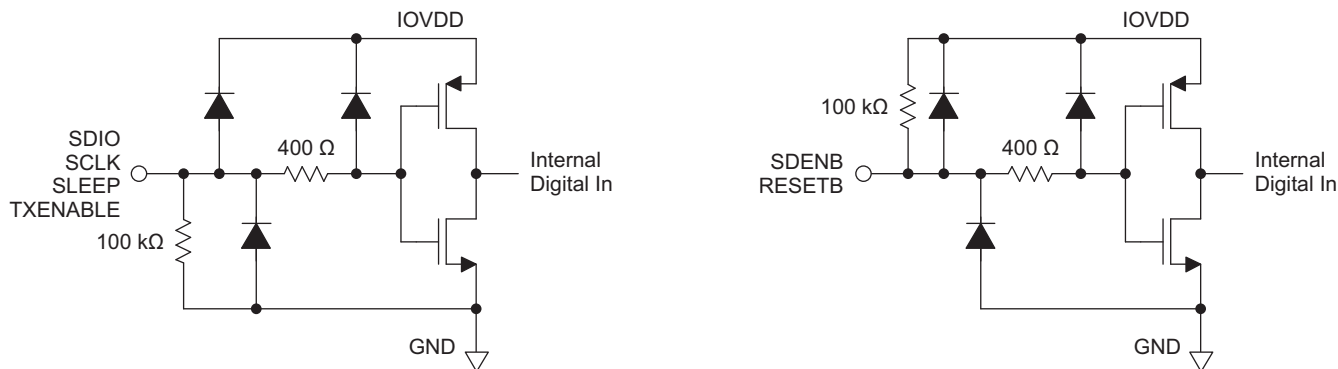

Figure 35. CMOS Digital Equivalent Input

REFERENCE OPERATION

The DAC3484 uses a bandgap reference and control amplifier for biasing the full-scale output current. The full-scale output current is set by applying an external resistor R_{BIAS} to pin BIASJ. The bias current I_{BIAS} through resistor R_{BIAS} is defined by the on-chip bandgap reference voltage and control amplifier. The default full-scale output current equals 64 times this bias current and can thus be expressed as:

$$IOUT_{FS} = 64 \times I_{BIAS} = 64 \times (V_{EXTIO} / R_{BIAS}) / 2$$

The DAC3484 has a 4-bit coarse gain control *coarse_dac(3:0)* in the *config3* register. Using gain control, the $IOUT_{FS}$ can be expressed as:

$$IOUT_{FS} = (coarse\_dac + 1)/16 \times I_{BIAS} \times 64 = (coarse\_dac + 1)/16 \times (V_{EXTIO} / R_{BIAS}) / 2 \times 64$$

where V_{EXTIO} is the voltage at terminal EXTIO. The bandgap reference voltage delivers an accurate voltage of 1.2V. This reference is active when *extref_ena* = '0' in *config27*. An external decoupling capacitor C_{EXT} of 0.1 µF should be connected externally to terminal EXTIO for compensation. The bandgap reference can additionally be used for external reference operation. In that case, an external buffer with high impedance input should be applied in order to limit the bandgap load current to a maximum of 100 nA. The internal reference can be disabled and overridden by an external reference by setting the *extref_ena* control bit. Capacitor C_{EXT} may hence be omitted. Terminal EXTIO thus serves as either input or output node.

The full-scale output current can be adjusted from 30 mA down to 10 mA by varying resistor R_{BIAS} or changing the externally applied reference voltage.

DAC TRANSFER FUNCTION

The CMOS DACs consist of a segmented array of PMOS current sources, capable of sourcing a full-scale output current up to 30 mA. Differential current switches direct the current to either one of the complementary output nodes IOUTP or IOUTN. Complementary output currents enable differential operation, thus canceling out common mode noise sources (digital feed-through, on-chip and PCB noise), dc offsets, even order distortion components, and increasing signal output power by a factor of two.

The full-scale output current is set using external resistor R_{BIAS} in combination with an on-chip bandgap voltage reference source (+1.2 V) and control amplifier. Current I_{BIAS} through resistor R_{BIAS} is mirrored internally to provide a maximum full-scale output current equal to 64 times I_{BIAS}.

The relation between IOUTP and IOUTN can be expressed as:

$$IOUT_{FS} = IOUTP + IOUTN$$

We will denote current flowing into a node as – current and current flowing out of a node as + current. Since the output stage is a current source the current flows from the IOUTP and IOUTN pins. The output current flow in each pin driving a resistive load can be expressed as:

$IOUTP = IOUT_{FS} \times CODE / 65536$

$IOUTN = IOUT_{FS} \times (65535 - CODE) / 65536$

where CODE is the decimal representation of the DAC data input word

For the case where IOUTP and IOUTN drive resistor loads R_L directly, this translates into single ended voltages at IOUTP and IOUTN:

$VOUTP = IOUT1 \times R_L$

$VOUTN = IOUT2 \times R_L$

Assuming that the data is full scale (65535 in offset binary notation) and the R_L is 25 Ω, the differential voltage between pins IOUTP and IOUTN can be expressed as:

$VOUTP = 20mA \times 25\ Ω = 0.5\ V$

$VOUTN = 0mA \times 25\ Ω = 0\ V$

$VDIFF = VOUTP - VOUTN = 0.5V$

Note that care should be taken not to exceed the compliance voltages at node IOUTP and IOUTN, which would lead to increased signal distortion.

ANALOG CURRENT OUTPUTS

The DAC3484 can be easily configured to drive a doubly terminated 50 Ω cable using a properly selected RF transformer. Figure 36 and Figure 37 show the 50 Ω doubly terminated transformer configuration with 1:1 and 4:1 impedance ratio, respectively. Note that the center tap of the primary input of the transformer has to be grounded to enable a DC current flow. Applying a 20 mA full-scale output current would lead to a 0.5 Vpp for a 1:1 transformer and a 1 Vpp output for a 4:1 transformer. The low dc-impedance between IOUTP or IOUTN and the transformer center tap sets the center of the ac-signal to GND, so the 1 Vpp output for the 4:1 transformer results in an output between –0.5 V and +0.5 V.
